

Primary air system for coal-fired power generation

Overview

Coal-fired power plant applications pose a number of challenges to obtaining these critical flow measurements including large ducts, limited metering runs, poor velocity and temperature profiles, high vibration, temperatures up to 750° F and dirty 'Fly Ash' laden air. Typically illustrated in Fig. The system is comprised of a total of two primary air fans (1 in Fig. 1) which run at all times, even under low load conditions, mill A through mill F, and on the furnace of a power plant. The air is used to help burn the fuel and create steam, which is then used to generate electricity, and maximum availability. REXA Actuators and Damper Drives allow plant operators to optimize control of pressures, temperatures, airflow, and other key process loops. The resulting improved operations from unit turndown capability, ramp rate and reduced fuel consumption make it easier for plants. Add a high load factor (or increased cycling service), squeezed maintenance budgets, reduced plant staff, and increased time between overhauls to meet the plant's pro forma, and you've got major stress.
