## Overview

---

The platform included a microgrid switch, PV inverter, wind power inverter, diesel generator, controllable loads, metering, and a grid simulator to emulate the point of common coupling. The US Department of Energy defines a microgrid as a group of interconnected loads and distributed energy resources within clearly defined electrical boundaries that acts as a single controllable entity with respect to the grid. Unlike the traditional grid, which relies heavily on centralization, production, and control. As the energy shifts from one of centralized energy (consumer) and distribution to decentralized production and distribution (prosumer), sufficient energy networks operate either with the main electrical grid or independently, harnessing a mix of traditional and renewable. Energy microgrids can be the pillar on which smart energy structures and smart grids, including energy systems using multiple energy carriers, will be based. It can connect and disconnect from the grid to operate in grid-connected or island mode.
